ABSTRACT

The measurement of job-related stress and job satisfaction in teaching is important for both the present and future well-being of teachers. This study investigated the psychometric characteristics of the Quality of Teacher Work Life Survey (QTWL) and examined which factors can be addressed by the school counselor in working to improve teacher well-being. The QTWL Survey was completed by 251 teachers who rated their present degree of satisfaction and the degree of stress experienced in each of 36 job-related areas, such as salaries, time for preparation, relationships with parents, and student interest. The results suggest that job satisfaction and job stress for teachers are multidimensional rather than unidimensional in nature. Job satisfaction and job stress, as measured by the QTWL, appeared to be strongly related. Overall job satisfaction and job stress for the teachers surveyed did not appear to be significantly related to most demographic variables. A slight but significant relationship may exist between satisfaction and educational level and between age and stress. Although further validation is needed, the QTWL holds promise as a measure of job satisfaction and job stress in teachers and as a diagnostic tool to help school counselors to focus staff development efforts to meet the specific needs of their teachers. (One figure and 13 tables are included.) (NB)

The Quality of Teacher Work Life Survey:
A Preliminary Report On a Measure of
Teacher Stress and Job Satisfaction and
the Implications For School Counselors

Introduction

The measurement of job-related stress and job satisfaction involved in teaching is an important consideration in both the present and future well-being of classroom teachers. A review of recently published articles on the topic of teacher stress and burnout demonstrates the increased interest in this area (Bando, 1979; Belcastro, 1982; Block, 1978, 1977; Cichon & Koff, 1980; Coates & Thoreson, 1976; Cook & Leffingwell, 1982; Fimian, 1985, 1982, 1980; Fimian & Santoro, 1983; Forman, 1982; Forsyth & Hav, 1978; Hendrickson, 1979; Johnson, Gold & Vicker, 1982; Kyriacou & Sutcliffe, 1981, 1978a, 1978b, 1977; Landsman, 1978, 1977; NEA, 1979; Newell, 1978; Schwab, 1981; Schwab & Iwanicky, 1982; Styles & Cavanagh, 1977; Youngs, 1978; Zabel & Zabel, 1982). Job satisfaction for teachers has likewise been the focus of a considerable amount of attention and research (Chapman & Lowther, 1982; Haughey & Murphy, 1983; Madinen, 1982; Owvamanan, 1984; Wallius, 1982).

While the significance of these two areas has been generally accepted, the methods for defining and measuring them have varied widely from study to study. The majority of studies have either

discussed the problem only in general terms or employed univariate variables to identify the causes. Most researchers developing their own instruments to measure job stress and job satisfaction limit their efforts toward demonstrating the psychometric qualities of the instrumentation, and fail to provide support for the validity of their measures.

School counselors in their day-to-day work with teachers must learn to appreciate not only the factors related to teacher stress and job dissatisfaction, but what they can do to improve the quality of work life for teachers. Cunningham (1983) in a review of the subject of teacher stress and satisfaction describes the importance of quality of teacher work life programs as a means for reducing or eliminating teacher stress and burnout. Evidence exists that improvements in the quality of work life leads to greater productivity as well as greater job satisfaction (Ford, 1969; Glaser, 1976; Mills, 1978; Stein & Kanter, 1980). Although the connection between job dissatisfaction and job burnout has been suggested it is unlikely that job stress is simply another term for job dissatisfaction (Maslach & Jackson, 1981). It is apparent that the work climate, structure and facets inherent in teaching directly influences the quality of work life through the amount of stress and the degree of satisfaction experienced by the individual. Through the school counselor's involvement QTWL programs can encourage attainment of higher ordered needs (i.e., self-actualization, personal worth and importance) while reducing

the levels of stress and dissatisfaction found in teaching. These efforts in turn yield higher levels of physical/mental health and emotional well being.

Thus far, no attempt has been made to measure the quality of teacher work life as it relates to job satisfaction and job-related stress, nor what school counselors can do as a resource to teachers in this area.

The primary purpose of this study was to investigate the psychometric characteristics of the Quality of Teacher Work Life Survey and to determine which factors can be addressed by the school counselor in working to improve the general well-being of teachers. The Quality of Teacher Work Life in this study is defined as the combined score of both the rating of perceived satisfaction with specific aspects of the teaching profession and the degree of perceived stress experienced with these aspects.

Method

Instrument

The Quality of Teacher Work Life Survey consists of 36 items which are used to measure satisfaction and stress. The items were selected on the basis of previous studies in this area (Coates & Thoreson, 1976; Kyriacou & Sutcliffe, 1978) as well as judgments made by the authors of this article as to the hypothesized aspects of the quality of teacher work life. Following the lead of the Hassles Scales (Lazarus & Cohen, 1977) and the Maslach Burnout Inventory (Maslach & Jackson, 1981) each statement is rated on two

dimensions: Satisfaction and stress experienced. The satisfaction scale is labeled at each point and ranges from 1 ("very dissatisfied") to 5 ("very satisfied"). The stressed scale ranges from 1 ("extreme stress") to 5 ("no stress"). The purpose for requesting two such ratings is based on the assumption held by the authors and others (Maslach & Jackson, 1981) that stress experience is not simply a synonym for job dissatisfaction. The total of these ratings produces an overall Quality of Teacher Work Life score.

Procedure

Each participant was asked to write the appropriate number representing their present degree of satisfaction and the degree of stress experienced in each of a number of job-related areas, e.g., salaries, time for preparation, relationships with parents, and student interest.

Participants

The QTWL Survey was sent to 511 Certified staff members from a school district located in the midwest. Additional materials were also distributed at this time as part of a larger research project. Surveys were sent out in April, 1984, and returned in May, 1984. Usable responses were received from 251 Teachers (49%). Demographic information for the subjects is presented in Table 1. For subjects completing the study the mean age was approximately 40 years (ranging from 22 to 65 years of age). Almost 75% of the respondents were female. Over 55% of the

subjects held at least a Master's degree. The sample was divided equally between elementary and junior high/high school levels. The mean years of employment in public schools was approximately 12 years with the number of years in the district almost 10. Overall the subjects were positive as to questions concerning their job. Eighty-seven percent (87%) said that "yes", they were planning on remaining employed in the public schools, 84% stated "yes", their reasons for originally choosing a career in education had been fulfilled, and almost 79% stated that they were "mostly to very satisfied" with their present position. Approximately 62% stated that if they had the choice to "reconsider" they would still choose education as a career.

Insert Table 1 about here

Results

The means, standard deviations, reliability coefficients, Cronbach's alpha, and standard errors of measurement are presented in Table 2.

Insert Table 2 about here

The reliability coefficients for the Satisfied, Stressed, and Quality Scales, respectively, are 0.89, 0.92, and 0.91. The correlation between the Satisfied and Stressed Scale was shown to

be 0.74. Correlations between the scales and selected demographic variables are shown in Table 3.

Insert Table 3 about here

Table 4 shows the correlation between the Stressed Subscale factors and the subscales of the Maslach Burnout Inventory. All correlations were found significant, though moderate, and in the predicted direction. Note that the higher correlations are found between the three QTWL scales and the frequency scales of both the Depersonalization and Emotional Exhaustion Subscales.

Insert Table 4 about here

In addition to answering the QTWL Survey, respondents were asked to rate their overall level of satisfaction with their jobs. This rating was also correlated with the QTWL scales. Findings indicated that the Total Quality Scale correlated .20 with general satisfaction ($p < .001$), while the Satisfied Subscale correlated .25 with the general satisfaction item ($p < .001$). Correlations between the ten factors of the Satisfaction subscale and the general satisfaction item ranged from .05 for the Time factor to $r = .28$ for the Students Factor (see Table 5). So, generally, correlations between the general satisfaction item and the

separate factors of the Satisfied Subscale were low to moderate, though significant for eight of the ten factors.

Insert Table 5 about here

It is expected that separate instruments designed to measure different constructs would yield little or no correlations between them. This is the definition of discriminant validity and is an important analysis in assessing the validity of a new measure (Campbell & Fiske, 1959). Discriminant validity of the QTWL was assessed by correlating it with the VAL-Ed, a measure of values regarding shoulds of interpersonal relationships in the school setting among children, teachers, administrators and the community. The VAL-Ed is based on FIRO theory (Schutz, 1967) and yields scores in areas of Inclusion, Control, and Affection on both feeling and behavioral levels, plus two scales relating to the importance of education and the purpose of the school. Harrington, Pelsma, and Richard (1985) analyzed the relationship between the VAL-ED and the Maslach Burnout Inventory and concluded that the MBI and the VAL-ED are not measuring the same psychological constructs. Therefore, it is safe to assume that assessing the relationship between the VAL-ED and the QTWL would provide evidence of discriminant validity. As Tables 6, 7, and 8 indicate, although approximately one-fourth of the correlations were found to be significant, most of them are very low and the

meaningfulness of the relationship may be suspect. As a result, it may be safe to assume that discriminant validity of the QTWL can be tentatively supported.

Insert Tables 6, 7, and 8 about here

A factor analysis using varimax rotation was conducted on the two scales, as well as the combined scale of the QTWL. The factor loadings for these scales are presented in Tables 9, and 10, and 11, respectively.

Insert Tables 9, and 10, and 11 about here

Ten factors were identified on each of the Satisfied Scale, the Stressed Scale and the Quality Scale. A listing of the factor names is presented for the scales in Table 12.

Insert Table 12 about here.

The ordering of the factors was different for the scales. However, items appeared to cluster fairly consistently into these general areas. The items that make up each factor for the Quality Scale is shown in Table 13.

Insert Table 13 about here

Implications for Counselors

Scores are provided to individuals in profile form. This way it is possible to determine which areas assessed by the QTWL are creating problems for the individual. This would furnish a way for counselors to determine where to focus their attention.

Analysis of individual items can give further information as to what the teacher perceives as stressful or dissatisfying. Also, an overall profile can be given to the school that would indicate the existence of any major problems, thereby providing the counselor or consultant with a starting point for understanding those problems, as well as an indication of where to intervene.

Conclusions

Although the sample in this study is small and more research is needed, the results of the present study suggest at least four general conclusions.

1. Job satisfaction and job stress for teachers appears to be multidimensional rather than unidimensional supporting the previous findings (Rogers, 1977; and Kyriacou & Sutcliffe, 1978a). The dimensions in the QTWL Survey are almost identical for all three scales and include factors related to: Administration, interruptions, time, external and internal support, students, work environment, extrinsic rewards, the job market, and evaluation. Figure 1 represents a model for the visual representation of these factors

affecting the quality of teacher work life.

Insert Figure 1 about here.

2. Job satisfaction and job stress, as measured by the QTWL, do appear to be strongly related. However, as previously stated by Maslach and Jackson (1981), job stress is not simply a synonym for job dissatisfaction. It is possible that some job related areas associated with low job satisfaction may not be producing job stress. The correlation between these scales is 0.74 which suggests the strongly related but unique aspects of each scale.
3. Overall job satisfaction and job stress for the teachers in our sample do not appear to be significantly related to most demographic variables (i.e., age, sex, education, or level of teaching). However, a slight (but significant) relationship may exist between satisfaction and educational level (the higher the educational level the lower the job satisfaction) and between age and stress (the older the individual the more stress experienced). These results need further clarification.
4. The development of the QTWL was based on the need for an instrument to assess both job satisfaction and job stress in teachers. Its potential use as a means of evaluating the quality of work life at the local level holds promise for

suggesting specific modifications and interventions to improve this important area. Provided with diagnostic information on the nature of perceived quality of work life for teachers, school counselors can focus their staff planning and development efforts to meet the specific needs of their teachers.

The instrument is still in its infancy, and analysis of its psychometric properties must continue. A larger sample size is needed to perform a complete validation of the Quality of Teacher Work Life Survey. Also, this research did not involve a rigorous validation procedure, such as the Multitrait-Multimethod approach outlined by Campbell and Fiske (1959), although some of this data has been collected. Interested persons are invited to contact the authors for more information concerning further validation of the instrument.
